First Edition, January 2026.

To R.A.W.

Who taught that the vacuum is not empty, but merely highly conductive.

Preface: The Engine Room

In *Flavor from Geometry* (Volume I), we constructed the map. We explored the static, seven-dimensional manifold connecting geometric fibers to particle identity. It was a study of structure—the *what* of reality.

This volume, *Geometry in Action*, is about the *how*. It is the study of flow.

Structure, left to itself, is inert. Physics requires action. The central premise of this volume is that the geometric structures defined previously act as a conductive medium. They possess a property we call ***Geometric Stiffness*** (β).

Where geometry is rigid, flow is constrained. Where geometry is pliable, flow becomes instantaneous.

This perspective is not entirely new. It is a translation of magnetospheric plasma physics—specifically the Rice Convection Model (RCM)—applied to new domains. In the RCM, ionospheric conductance dictates the flow of plasma in near-Earth space. In this volume, we apply that same convective logic to two vastly different scales: the macroscopic transport of photons (Rendering) and the microscopic confinement of quarks (QCD).

The first half of this book is a computational proof. It lays bare the source code of the WTS-RT protocol, demonstrating how treating light as a symplectic fluid allows us to solve global illumination in constant time relative to scene complexity. It is the engineering validation of the theory.

The second half applies this "engine" back to the hadronic sector, proposing that the mass gap and jet formation are merely consequences of a vacuum that has finite stiffness.

If Volume I was the blueprints, Volume II is the machine running at full RPM.
